Symposium
I.Family: Health and development of small children
Observations from the IDEFICS-I.Family Cohort

Pre- and perinatal influences on the weight status of primary school children
Wolfgang Ahrens (Bremen, Germany), Alfonso Siani (Avellino, Italy)

- on behalf of the I.Family consortium -
Identification and prevention of Dietary- and lifestyle-induced health Effects in children and infants

A European epidemiological study to understand & prevent childhood obesity & related disorders

EU 6th Framework Programme
Thematic Priority 5: Food Quality and Safety (3rd Thematic Call; July 2004)
Area 2: Epidemiology of food-related diseases and allergies Topic 5.4.2.1: Influence of diet and lifestyle on children’s health (Integrated Project)
Sept. 1st 2006-Feb. 28th 2012
Participating countries

- Normal weight: 69.4%
- Overweight: 12.7%
- Obese: 7%
The IDEFICS parental questionnaire

Data on prenatal, perinatal and early postnatal factors were collected by means of standardized parental questionnaires.

- birth weight (g)
- maternal gestational weight gain (kg)
- age of the mother during pregnancy (years)
- smoking (number of cigarettes per day) of the mother during pregnancy
- alcohol intake (number of alcohol consumptions per day) of the mother during pregnancy
- maternal obesity (categorical: yes/no)
- age of onset of maternal obesity (years)
- education level of the mother
- education level of the father
- time of delivery
- presence of gestational diabetes
- presence of gestational hypertension
Focus on risk factors:

Prenatal
• Smoking during pregnancy
• Gestational weight gain
• Gestational diabetes

Perinatal
• Birth weight
• Caesarian section

Postnatal
• Breastfeeding (initiation and duration)
• Early introduction of solid foods
• Gestational weight gain

**Gestational weight gain and adiposity, fat distribution, metabolic profile, and blood pressure in offspring: the IDEFICS project.**

**OBJECTIVE:** To investigate the association between gestational weight gain (GWG) and total adiposity, body fat distribution, blood pressure (BP), and metabolic profile in offspring.

**DESIGN:** Cross-sectional study.

**METHODS:** Body mass index (BMI), waist, subscapular and tricipital skinfolds, and BP were measured and blood samples drawn in 12,775 children (aged 2–9 years) from the IDEFICS cohort. Overweight/obesity was defined by IOTF criteria. Parents filled in a questionnaire investigating child and familiar medical history and lifestyle. A section was dedicated to pregnancy history (including GWG).

<table>
<thead>
<tr>
<th>GWG tertiles</th>
<th>I (n=5330)</th>

<tr>
<td>Mother GWG (Kg)</td>
<td>10 (8-11)</td>
<td>14 (13-15)</td>
<td>20 (18-24)</td>
</tr>
</tbody>
</table>
RESULTS: Anthropometric indices linearly and significantly increased across GWG tertiles (BMI z-score: tertile I=0.08, 0.03–0.13; tertile II=0.16, 0.12–0.21; tertile III=0.34, 0.28–0.40, P<0.01, mean, 95% CI) by analysis of covariance (ANCOVA), adjusted by child sex, age and practice of sport, birth weight, current maternal BMI, parental education, gestational age, age at delivery, alcohol and smoking during pregnancy, maternal diabetes mellitus, gestational hypertension, and breastfeeding duration. The adjusted risk of overweight/obesity significantly increased by 14% and 22% in tertiles II and III respectively, in comparison with tertile I by logistic regression analysis controlling for covariates.

CONCLUSION: Maternal GWG is an independent predictor of total adiposity and body fat distribution in offspring during infancy. Exposure to perinatal factors should be taken into account for early prevention of overweight and obesity.
OBJECTIVE: Fetal macrosomia is a risk factor for the development of obesity late in childhood. We retrospectively evaluated the relationship between maternal conditions associated with fetal macrosomia and actual overweight/obesity in the children participating in the IDEFICS study.

METHODS: Anthropometric variables, blood pressure and plasma lipids and glucose were measured. Socio-demographic data, medical history and perinatal factors, familiar and gestational history, maternal and/or gestational diabetes were assessed by a questionnaire. Variables of interest were reported for 10,468 children (M/F=5,294/5,174; age 6.0±1.8 yrs, M±SD). The sample was divided in four groups according to child birth weight (BW) and maternal diabetes: (1) adequate for gestational age offspring (BW between the 10th and 90th percentiles for gestational age) of mothers without diabetes (AGA-ND); (2) adequate for gestational age offspring of mothers with diabetes (AGA-D); (3) macrosomic offspring (BW>90th percentile for gestational age) of mothers without diabetes (Macro-ND); (4) macrosomic offspring of mothers with diabetes (Macro-D).

RESULTS: Children macrosomic at birth showed significantly higher actual values of body mass index, waist circumference, and sum of skinfold thickness. In both boys and girls, Macro-ND was an independent determinant of overweight/obesity, after the adjustment for confounders [Boys: OR = 1.7 95 % CI (1.3;2.2); Girls: OR = 1.6 95 % CI (1.3;2.0)], while Macro-D showed a significant association only in girls [OR = 2.6 95 % CI (1.1;6.4)].

CONCLUSIONS: Fetal macrosomia, also in the absence of maternal/gestational diabetes, is independently associated with the development of overweight/obesity during childhood.
**Breastfeeding (initiation and duration)**

**Early introduction of solid foods**

**Infant feeding practices and prevalence of obesity in eight European countries - the IDEFICS study.**

Public Health Nutr. 2013 Feb;16(2):219-27

**OBJECTIVE:** To assess the association between exclusive breast-feeding and childhood overweight.

**DESIGN:** Cross-sectional data are from the baseline survey of the longitudinal cohort study IDEFICS. Exclusive rather than partial breast-feeding is the focus of the study due to the theoretical relationship between exclusive breast-feeding and development of dietary self-regulation. Children’s measured heights and weights were used to calculate weight status.

**SETTING:** Examination centres in eight European countries (Italy, Estonia, Cyprus, Belgium, Sweden, Hungary, Germany and Spain).

**SUBJECTS:** The analysis included 14 726 children aged 2–9 years for whom early feeding practices were reported by parents in standardized questionnaires.
RESULTS: After controlling for education, income and other potential confounders, breast-feeding exclusively for 4–6 months was protective of overweight (including obesity) when compared with children never exclusively breast-fed (OR=0.73; 95% CI 0.63, 0.85) across all measures of overweight. Exclusively breast-feeding for 6 months offered slightly more protection than for 4 and 5 months combined (OR=0.71; 95% CI 0.58, 0.85). The associations could not be explained by socio-economic characteristics or maternal overweight.

CONCLUSIONS: This multi-country investigation indicated that exclusive breastfeeding for 4–6 months may confer protection against overweight in addition to other known benefits. There was no demonstrated benefit of exclusive breastfeeding for more than 6 months or combination feeding for any duration across all measures of overweight examined.
Breastfeeding (molecular bases)

BACKGROUND: Blood-cell transcripts have showed to be good biomarkers of metabolic alterations and their use in early detection and prevention of future disorders is promising. OBJECTIVE: This study aimed to examine the relation between previously proposed transcriptional biomarkers of metabolic health (SLC27A2, CPT1A, FASN, PPARα, INSR, LEPR) in peripheral blood cells and type of infant feeding in a subset of children from the IDEFICS cohort. SUBJECTS: A total of 237 children aged 2–9 years from eight European countries were studied. 
RESULTS: Breastfed children showed higher expression levels of SLC27A2, FASN, PPARα and INSR, and lower risk of being overweight and of having high plasma triglyceride levels vs. formula-fed children. Besides, overweight formula-fed children presented higher HOMA-index than overweight breastfed children (1.90 vs. 1.62); however, this negative effect was absent in formula-fed children with high expression of SLC27A2. Moreover, formula-fed children with low expression of SLC27A2, FASN, PPARα and INSR presented higher triglyceride levels than subjects with high expression of these genes (77.7 mg/dL vs. 44.8 mg/dL). This difference was absent in breastfed children.

CONCLUSIONS: Protective effects of breastfeeding are reflected in higher expression levels of SLC27A2, FASN, PPARα and INSR in blood cells.

What this study adds
- Children who had been breastfed showed higher expression levels of SLC27A2, FASN, PPARα and INSR in PBCs compared with formula-fed subjects.
- The relationship of the PBC transcript levels of SLC27A2, INSR, FASN and PPARα with insulin resistance and dyslipidaemia may be dependent on the type of infant feeding (breast vs. formula).
- The transcript levels of the mentioned biomarkers could be useful to distinguish the formula-fed children who are at higher risk of metabolic alterations.
The early life course is assumed to be a critical phase for childhood obesity; however the significance of single factors and their interplay is not well studied in childhood populations.

OBJECTIVES: The investigation of pre-, peri- and postnatal risk factors on the risk of obesity.

METHODS: A case-control study with 1,024 1:1-matched case-control pairs was nested in the baseline survey (09/2007–05/2008) of the IDEFICS study, a population-based intervention study on childhood obesity carried out in 8 European countries in pre- and primary school settings. Conditional logistic regression was used for identification of risk factors.

RESULTS: For many of the investigated risk factors, we found a raw effect in our study. In multivariate models, we could establish an effect for gestational weight gain, smoking during pregnancy, Caesarian section, and breastfeeding 4 to 11 months. Birth weight was related to lean mass rather than to fat mass, the effect of smoking was found only in boys, but not in girls. After additional adjustment for parental BMI and parental educational status, only gestational weight gain remained statistically significant. Both, maternal as well as paternal BMI were the strongest risk factors in our study, and they confounded several of the investigated associations.

CONCLUSIONS: Key risk factors of childhood obesity in our study are parental BMI and gestational weight gain; consequently prevention approaches should target not only children but also adults. The monitoring of gestational weight seems to be of particular importance for early prevention of childhood obesity.
